

# Sisyphus' Schedule

A Workout App to schedule workout splits, explore exercises, and track calories.

Tesla Norton, Lily Brongo, Thomas Hinckley, Nolan Nachbar, Collin Davis

Team Name: Flex Appeal

## Overview

Problem: It allows people to avoid stress about planning their workouts every day. It will enable users to experiment with different splits and workouts to find the best workout for

2 main parts - Workout Schedule & Food Management

User creates a profile with Gender, Age, Weight, and Experience (beginner, intermediate, professional)

User selects desired goal (Bulk, Cut, Tone, etc.) and/or areas they'd like to work on

Based on the user, provide an appropriate split schedule (leg day, back and bis, push/pull days), provide a calorie goal, and log (like Fitness Pal)

Allow the user to love/hate an exercise to implement or substitute a movement the user likes best. For example, if a user is on leg day and they hate Bulgarian split squats, the app would substitute that movement for another exercise that targets the same muscle.

(potential stretch goal) Implement a rating system from other users and professional sources of different splits, exercises, and meals.

them. It will also enable newbies to have an idea of where to start and grow from there. It also makes tracking calories easier. This will be a website and phone app that has everything in one app, so users are not bouncing between multiple apps just to track their fitness goals.

## Possible Functionality

1. Customize an exercise bank where your automated split will choose from
2. Adjust your plan based on user-rated fatigue and the lifts (weights, sets, and reps) the user hits
3. Automate progressive overload - reps, sets, weight
4. Custom volume (sets, reps, frequency) preference
5. Customize your desired proximity to failure (RPE or RIR, maybe)
6. Easily swap out exercises before/during lift if a machine is taken or if you don't like an exercise
7. Adjust workouts based on macrocycles, mesocycles, microcycles, or workout to workout, based on user preferences
8. The app will recommend/adjust frequency based on the user's recovery
9. You can rate a muscle's soreness and overall CNS fatigue, and it'll adjust your frequency based on that.
10. Add recovery splits and days
11. Enable different styles of working out (weight lifting, biking, running, walking, swimming, calisthenics, and any others we think of down the road).

## Timeline

- End of October: Have a complete idea of the web application/phone app from layout to idea of what we will build. Start with our resource research and getting all the data we need for the idea.
- End of November: Have all our resources chosen and ready to start building. Start UI development. Start AI development/machine learning once all resources are found.
- Before Christmas Break: UI is almost complete. Start working on the functionality for the app.
- End of January: Have functionality of the app mostly done.
- End of February: Have functionality done. Start debugging process.
- End of March: Have the project done and start preparing for the presentation.

- Within March and April we will spend time working with users and get their feedback
- By Deadline: We are finally done.

## User Testing

Within our time line we will need to implement tests that focus on not only the user experience but also our functionality. We will use a week time period at the end of March to the beginning of April to allow users to get the full experience and customizable options of the workouts. We will need to see what works best and what does not work for our testers. Whether that may be specific applications we have, such as the choices in workouts, the meal tracking, and bugs that we were unable to catch. We will use pre and post questionnaires to receive feedback and will continue with scenario maps and user experience techniques to help us determine if our app truly provides the accessibility and functionality that we want to provide.

### Day 1: March 29th

Give users the prequestionnaire (asking what they are looking to gain from the application, where they are starting from...)

Walk users through the app set up and let them get involved with the application

### Day 2: March 30th

Check in with users and see if they are happy with their provided workout/split given for the week. If there were any bugs and issues that they have run into, note them and continue with the trial.

### Day 3: March 31st

See if any of the users have made changes to their workouts or splits. Inquire about the food tracking, if it's been used, if there are issues, if there is something they tried to track but were unable to. See how the recommendations have affected and impacted the user.

### Day 4: April 1st

No check in, allow users to continue with the trial but allow for feedback at any time whether through direct contact or a form submission available throughout the trial. Work on potential fixes for the immediate issues presented.

Day 5: April 2nd

Allow for freedom to users, same as day before.

Day 6 (Final Day): April 3rd

Collect data and give post questionnaires. Allow for discussion between users and developers to see which aspects were their favorites and which they did not like. Free expression and communication of feelings/thoughts towards the application.

## Framework and Language

We will be using HTML, CSS, and JavaScript for all the front-end and functionality of the project. We will be using Python (for machine and AI development) and API calling for the project's backend.
